Letter to the Editor: Biomechanics of Childbirth

Dear Editor,

With great interest, I read the paper published in your journal on the 3rd of May, entitled “Bouncing your way to labour and birth using biomechanics and foetal optimal positioning”, and authored by Roisin Lennon (Lennon, 2024).

While I appreciate the alternative approach and the effort to link biomechanics with foetal positioning to facilitate labour, I have concerns regarding the usage and interpretation of the term 'biomechanics' within the context of the article. Also, there are many misleading parts and a potential level of bias.

Biomechanics:

Biomechanics, as a discipline, involves the scientific study of the mechanical laws relating to the movement or structure of living organisms. It encompasses not only the techniques to measure forces that act upon and within biological systems, such as the human body, but also the analysis of the mechanics of living organisms and the application of engineering principles to and from biological systems. This can include studying how muscles, bones, tendons, and ligaments work together to produce movement, and how external forces, like gravity or the environment, impact biological functions (Innocenti, 2018; Knudson & Knudson, 2007; Robertson et al., 2013). If I were to give a simple definition of what the biomechanics of childbirth is, I would say: The biomechanics of childbirth refers to the study of the mechanical processes and physical forces involved during labour and delivery. It encompasses how the birthing person’s body and the foetus interact and adapt to facilitate childbirth.

Based on the above, we can only say “biomechanics of birth” and not “biomechanics for birth”, as the use of “of” refers to the study and analysis of the mechanical processes and forces involved in childbirth. However, the author throughout the paper uses the phrase “biomechanics for birth” and “biomechanics for birth toolkit”, mainly referring to techniques and manoeuvres to assist childbirth (Lennon, 2024). Even if the word “for” is used intentionally to shift the focus towards an external application or intervention designed to achieve or assist in childbirth, this can be misleading. It implies a practical or utilitarian approach rather than a scientific analysis which is what biomechanics is (Robertson et al., 2013). Sometimes in several fields like physiotherapy and sport sciences, the term biomechanics is used to refer to methods and techniques, but an additional difference for these fields is that there are biomechanical studies to support the use of these manoeuvres, techniques, implementations, and tools (Chaffin et al., 2006; Hay, 1978; Morris, 1977). It is crucial to highlight that to date there is not even one biomechanical study conducted during labour, a topic which I will elaborate on further below. The author of this letter has conducted a scoping review, with the last search until August 2021, which is currently being updated before submission, to be certain that there is not even one kinematic, kinetic, or other biomechanical type study, other than computational modelling. Therefore, the use of “for” misconstrues the fundamental principles and methodologies of biomechanics.

Areas of Concern:

- The title says “using biomechanics” although the author did not use biomechanics.
- In the introduction, the author states, “With advances in three-dimensional models of the human body exploring how it works and moves, there has been a rise in different professionals investigating the workings of the pelvis during labour and birth. This has provided maternity healthcare professionals with a better understanding of the effects of pregnancy hormones and the biomechanical changes that affect the abdominal muscles and spinal curvatures,” using as reference the systematic review conducted by Conder et al. (2019). This review aims to explore the effects of pregnancy on the biomechanics and anthropometrics of the body and how this results in altered posture, stability, and gait patterns that influence the body. This again confirms, as stated above, that conditions, movements, in this case pregnancy, affect the biomechanics of the body, and not the biomechanics for pregnancy or birth. Furthermore, the authors of the systematic review included studies during the antenatal period only (Conder et al., 2019). Therefore, the author cannot use this reference in the introduction and claim that “there has been a rise in different professionals investigating the working of the pelvis during labour and birth,” as labour and birth are not part of this systematic review. In fact, as mentioned above, to date, there is not even one study published using biomechanics conducted during childbirth. The reason for this is that the usual methods for kinematic and kinetic analysis cannot be used during labour, as markers have to be placed in several locations that cannot be removed or covered. In addition, the labouring person will not be able to lie due to the markers on the spine, hips, etc. Additionally, approximately 12 cameras on heavy-duty tripods have to be set up in the labouring ward, along with processing, synchronisation, and filtering units. These are just some of the limitations among many for why the currently available techniques cannot be used during childbirth and, therefore, why we do not have even a single study during childbirth (Desseauve et al., 2017; Desseauve et al., 2019; Desseauve et al., 2020; Szczerbik et al., 2011; Topley & Richards, 2020). Recently, markerless methods have been developed, but again due to other limitations, they cannot be used (Tang, 2023; Wade et al., 2022). Also, the hardware setup with cameras and processing units is quite similar. Finally, furniture, equipment, and medical professionals cannot come between the marker and the recording camera or cover it with their hands in an attempt to provide care. These are just some simplified examples of why we do not have a study yet.
- Following this section, the author of this paper states, “These studies have demonstrated that obstructed labours are a mechanical imbalance in the pelvis that results in the fetus’ position not being the best fit to negotiate the pelvis (Hemmerich et al 2019; Grimm, 2021; O’Brien, 2023).” The first study by Hemmerich et al. (2019) is a computational modelling study. Since we cannot use other techniques to date, biomechanists and bioengineers worldwide work with computational modelling techniques, including finite element analysis, to understand childbirth. However, computational models and simulations have their well-known limitations, assumptions, and simplifications. The models are usually subject-specific, represent only a specific condition and situation, and many factors are either treated as assumptions or cannot be computed (Beller et al, 2010; Kasiteropoulou et al., 2020; Parente et al., 2010; Parente et al., 2010). The authors of this study (Hemmerich et al., 2019) have made significant contributions to the area of biomechanics of pregnancy and childbirth with many well-known studies (Cripton et al., 2001; Moorcroft et al., 2003; Hemmerich et al., 2018). In their referenced study, they clarify all limitations and highlight the importance of *in vivo* data (Hemmerich et al., 2019). It is important to understand that while computational modelling is a great way to investigate complex situations, it provides basic knowledge, and the results might not be representative of any specific individual. The second reference is an

excellent work by Grimm (2021), which uses computational models as part of a comprehensive approach to understanding the biomechanics of childbirth. This study provides a macro-level explanation, attempting to bridge detailed biomechanical knowledge (such as forces acting during childbirth) with larger-scale physiological processes. However, as stated above, these are again computational model studies. The third reference is a work published by O'Brien M 2023, which introduces "biomechanics for birth", which appears to be techniques and manoeuvres integrated into the education curriculum. Therefore, these references are not the most appropriate for the statements in that section.

- Just after this, the author states, "Upright positions, squatting and mobilising maximise the effect of gravity and the effectiveness of contractions," using as a reference the published study by O'Brien et al. (2022), which is a mixed-method study, mostly with qualitative data about midwives' experiences of implementing the Labour Hopscotch Framework. How, from this study, can the author of this paper claim "Upright positions, squatting and mobilising maximise the effect of gravity and the effectiveness of contractions"? Was gravity assessed or analysed as part of O'Brien et al. (2022) paper? No! Were data from tocodynamometers or internal uterine pressure catheters, or electromyography or even palpation collected, analysed, and used to assess the effectiveness of contractions? Again, no! There is only one quote by a midwife mentioning contractions.

These are just some examples of misleading information used in this paper, inadequate referencing, and biased writing.

- Furthermore, it is surprising that pregnancy records, including birth outcomes, were collected, which constitutes clinical data, without requiring Ethical Review and Approval for this study. Moreover, an alteration to usual practice was applied with the introduction of an unvalidated toolkit, yet again, no ethical approval was required. In addition, the methodological design, missing variables (such as ethnicity), no reporting on data access, management, and storage of both personal and clinical data, do not align with the basic principles of 'Good Research Practice' and exhibit a level of bias, potentially leading to the predefinition of results.
- Finally, the author states, "All participants received continuity of care from the advanced midwife practitioner with biomechanics, exercise, and labour hopscotch being discussed at each appointment from 26 weeks on." This raises important questions about the content and basis of these discussions. Specifically, given the limited knowledge in the biomechanics of childbirth, primarily derived from computational models, what specific biomechanics were discussed? Additionally, what knowledge or relevant qualifications does the author, an advanced midwife practitioner, have to effectively discuss biomechanics?

Apart from the above, I would appreciate further details on the biomechanical models and theories that underpin these interventions. Specifically, it would be enlightening to understand the biomechanical scientific basis and actual biomechanics for the exercises and manoeuvres recommended in the toolkit, beyond observations and experiential knowledge, and how these directly influence the mechanical environment of the pelvis during labour. Providing any evidence-based information would greatly enhance the readership's understanding of the interplay between biomechanics and practical midwifery interventions, ensuring a more comprehensive appreciation of the alternative approaches being implemented to optimise natural childbirth processes.

It is essential for the readership to consider these aspects to avoid potential misinterpretations that could arise from the article. Future discussions in this area would benefit from including detailed

biomechanical analyses or references to peer-reviewed biomechanical research to clarify how these methods/approaches (such as the "biomechanics for birth toolkit" and "labour hopscotch") directly influence the physiological processes of labour.

Yours sincerely,
Dr Anastasia Topalidou

[Dr Anastasia Topalidou (BSc, BSc, MSc, PhD) specialises in the area of biomechanics of pregnancy and childbirth. Anastasia has extensive experience in musculoskeletal and clinical biomechanics, thermal imaging, and the use and development of non-invasive methodologies and techniques, devices, and innovations. Anastasia leads the IMAGES (Biomechanics and Imaging Research for Maternal Health and Neonates) group at the University of Central Lancashire and is the founder and chair of the INBIRTH Network (International Research Network for the Study of Biomechanics in Pregnancy and Childbirth)].
